

Keplerian Deadlock

Every pair of orbital planes intersects at exactly 2 points on the sphere.

Red dots = true 3D intersection points (20 for 5 orbits)

The crossing problem

- 5 orbits shown
- Each pair intersects at 2 points
- 5 orbits $\rightarrow$ 10 pairs $\rightarrow$ 20 crossings
- N orbits $\rightarrow N(N-1)$ crossing points

Collision management grows as $O(N^2)$

This is the Keplerian deadlock:
more coverage = more intersections
